

Basic Number Theory and Modulo Joy

Chapter 3

1. (a) Find integers x and y such that $17x + 101y = 1$

The way that you start this problem is using the Extended Euclidean Algorithm. You can go about that as follows. You can use the Extended Euclidean algorithm to find s and t of the following equation

$$as + nt = \gcd(a, n)$$

. So in our case $a = 17, n = 101, \gcd(a, n) = 1$. The first step is to do the Euclidean algorithm in order to find the quotients.

$$101 = 17 \cdot 5 + 16$$

$$17 = 16 \cdot 1 + 1$$

$$16 = 1 \cdot 16$$

Our quotients are 5, 1, 16. The extended Euclidean algorithm gives us a recursion in terms of the quotients q and s, t to find s_n and t_n . That is of the following form

$$x_0 = 0, x_1 = 1, x_j = -q_{j-1}x_{j-1} + x_{j+2}$$

$$y_0 = 1, y_1 = 0, y_j = -q_{j-1}y_{j-1} + y_{j+2}$$

Now knowing this equation we can solve for x_n where n is the last step in the Euclidean Algorithm.

$$x_0 = 0, x_1 = 1$$

$$x_2 = -5 \cdot 1 + 0$$

$$x_3 = -1 \cdot -5 + 1$$

Going through these same steps for solving y_n we get $x_n = 6$ and $y_n = -1$. Checking our answer we see that this indeed true.

- (b) Find $17^{-1} \pmod{101}$

To find the inverse of $17 \pmod{101}$. We need to find a number x that holds the following condition $17x \equiv 1 \pmod{101}$. If we look close at the equation from part (a). We can write it as the following

$$17x + 101y = 1$$

$$17x = 1 - 101y$$

$$17 - 1 = -101y$$

$$17 - 1 = 101 \cdot (-y)$$

$$17x \equiv 1 \pmod{101}$$

So x is 6 in other words $17^{-1} \pmod{101}$ is 6

2. (a) Solve $7d \equiv 1 \pmod{30}$

Similar to our solution to question 1. We need to use the Euclidean Algorithm to find the quotients then solve for the equation $as + nt = 1$ where $a = 7, n = 30$. Then d will be s .

$$30 = 7 \cdot 4 + 2$$

$$7 = 3 \cdot 2 + 1$$

$$3 = 1 \cdot 3$$

Now knowing this equation we can solve for x_n where n is the last step in the Euclidean Algorithm.

$$x_0 = 0, x_1 = 1$$

$$x_2 = -4 \cdot 1 + 0$$

$$x_3 = -3 \cdot -4 + 1$$

$$x_3 = 13$$

So $x_n = 13$, thus $d = 13$.

3. (a) Find all solutions of $12x \equiv 28 \pmod{236}$

First we start by seeing if the $\gcd(12, 236)$ is 1. The $\gcd(12, 236) = 4$. So in order to find the solution we must divide the equation by the $\gcd(12, 236)$ if 4 doesn't divide 28 then there is no solution. If it does then we solve the reduced equation for x . The resulting equation is: $3x \equiv 7 \pmod{59}$. The $\gcd(3, 59)$ is 1 so we solve like normal. Since the inverse of 3 $\pmod{59}$ is 20 we multiply both sides by 20. Which gives $x \equiv 140 \pmod{59}$. 140 Modulo 59 is 22. So $x \equiv 22, 81, 140, 199, 22 + 59 \cdot 5, \dots$

- (b) Find all solutions of $12x \equiv 30 \pmod{236}$. Since 30 is not divisible by 4. There is no solution

11. Let p be prime. Show that $a^p \equiv a \pmod{p}$ for all a . We can show this is true by using Fermat's Theorem. If we have $a^{p-1} \equiv 1 \pmod{p}$. We can multiply by a on both sides to get the formula. $a^p \equiv a \pmod{p}$. This holds for all a .

12. Divide 2^{10203} by 101. What is the remainder?

The question is asking for the remainder after dividing a number which is the same as asking for $2^{10203} \pmod{101}$. First notice that $2^{10203} = 2^{100 \cdot 102} \cdot 2^3$. So we can use Fermat's Theorem to simplify $2^{100} \equiv 1 \pmod{101}$. This gives us $1^{102} \cdot 2^3 \pmod{101}$. Which is equal to 8.

13. Find the last 2 digits of 123^{562} . Since we are looking for the last 2 digits of a number that is the same as getting the remainder of dividing by 100. Since 100 is composite we can use Euler's ϕ equation.

$$\phi(100) = 100 \cdot \left(1 - \frac{1}{2}\right) \left(1 - \frac{1}{5}\right) = 100 \cdot \frac{1}{2} \cdot \frac{4}{5} = 100 \cdot \frac{4}{10} = 40$$

.So we know that $123^{40} \equiv (\text{mod } 100)$

Using this we can conclude

$$123^{40 \cdot 14} \cdot 123^2 \equiv 1^{14} \cdot 123^2 \equiv 15129 \equiv 29 \pmod{100}$$

. Thus the last two digits are 29.
